All figures in this report have been saved using saveFigPDF function as it automatically resizes the paper to the correct size.

Listing 1: ../src/saveFigPDF.m

```
function saveFigPDF(fileName)
    %saveFigPDF saves open figure as a PDF file
    %
    %Inputs:
    % fileName = File name to save figure as
    %Usage:
    % saveFigPDF("polynomial") -> Saves current figure as polynomial.pdf

    % Get current figure handle
    figureHandle = gcf;
    % Resize paper
    set(figureHandle, 'PaperPosition', 3*[0 0 6 4]);
    set(figureHandle, 'PaperSize', 3*[6 4]);
    set(figureHandle, 'PaperUnits', 'centimeters');

    print(fileName, '-dpdf');
end
```

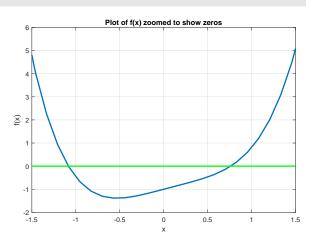

## Question 1: Root-finding

- (a) To find how many solutions each equation has in the given domain I will rearrange all the equations to be equal to zero and then looks for the roots of the rearranged equations. As a corollary to the intermediate value theorem, if a function is continuous and changes sign in an interval then that bracketing interval must contain a root. So I will plot each of the rearranged equation and look for bracketing intervals that contain a root. I will use the pltFunc function (as shown in Listing 30) to plot the functions as it removes values outside a defined limit which prevents MATLAB plotting discontinuous functions as continuous. The limits can then be changed using the property explorer to show more detail if needed.
  - (i) Rearranging  $x^4 = e^{-x}\cos(x)$  gives  $f(x) = x^4 e^{-x}\cos(x)$ .

Listing 2: ../src/q1/Q1a\_i\_funcPlt.m

```
f = Q(x) x.^4 - exp(-x).*cos(x);
pltFunc(f, [-2*pi 2*pi], inf);
```

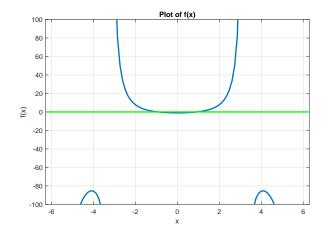

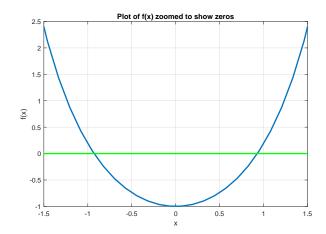

The second zoomed in plot shows there are two solutions in the given domain. The first root can be bracketed by the interval [-1.5, -1] as f(-1.5) = 4.7455 and f(-1) = -0.4687 so since the function is continuous and there is a change of sign this bracket must contain a root. Like wise the second root can be bracketed by the interval [0.5, 1] as f(0.5) = -0.4698 and f(1) = 0.8012.

(ii) Setting  $f(x) = \frac{x^3}{\sin(x)} - 1$ .

Listing 3: ../src/q1/Q1a\_ii\_funcPlt.m

```
f = Q(x) (x.^3)./\sin(x) - 1;
pltFunc(f, [-2*pi 2*pi], 500);
```

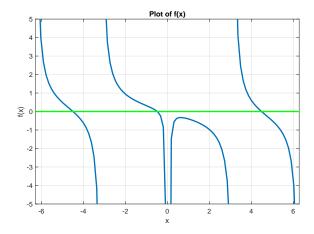

The second plot show there are two roots. The first root can be bracketed by the interval [-1, -0.5] as f(-1) = 0.1884 and f(-0.5) = -0.7393 and f(x) is continuous in this bracket. Likewise, the second root can be bracketed by the interval [0.5, 1] as f(0.5) = -0.7393 and f(1) = 0.1884.

(iii) Rearranging  $\cot(x) = \frac{25}{25x-1}$  gives  $f(x) = \cot(x) - \frac{25}{25x-1}$ .

Listing 4: ../src/q1/Q1a\_iii\_funcPlt.m

$$f = @(x) cot(x) - 25./(25*x - 1);$$
  
pltFunc(f, [-2\*pi 2\*pi], 30);

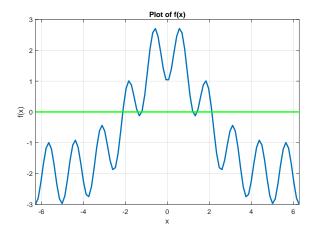

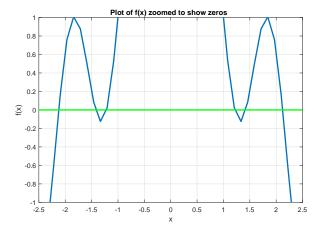

The plot shows that the equation has three solutions. The first can be bracketed by the interval [-5, -4] as f(-5) = 0.4942 and f(-4) = -0.6162. The second solution can be bracketed by the interval [-1, -0.1] as f(-1) = 0.3194 and f(-0.1) = -2.8238. The third solution can be bracketed by the interval [4, 5] as f(4) = 0.6112 and f(5) = -0.4974. f(x) is continuous in each of the bracketing intervals.

(iv) Rearranging  $4e^{-x^2/5} = \cos(5x) + 2$  gives  $f(x) = 4e^{-x^2/5} - \cos(5x) - 2$ .

Listing 5: ../src/q1/Q1a\_iv\_funcPlt.m

```
f = @(x) 4*exp(-x.^2/5) - cos(5*x) - 2;
pltFunc(f, [-2*pi 2*pi], inf);
```

The second plot shows that the equation has 6 solutions. The bracketing intervals are shown in the table below.

| [a,b]         | f(a)    | f(b)    |
|---------------|---------|---------|
| [-2.5, -2]    | -1.8518 | 0.6364  |
| [-1.5, -1.25] | 0.2039  | -0.0730 |
| [-1.25, -1]   | -0.0730 | 0.9913  |
| [1, 1.25]     | 0.9913  | -0.0730 |
| [1.25, 1.5]   | -0.0730 | 0.2039  |
| [2, 2.5]      | 0.6364  | -1.8518 |

(b) The bisection method is used by calling the the bisectRoot function.

Listing 6: ../src/q1/bisectRoot.m

```
function [sol, i, err] = bisectRoot(f, a, b, tol)
   %bisectRoot Use the bisection method to find roots of the function f
   % bracketed within the intervals [a, b].
   %Inputs:
   \% f = function handle to function whose root is to be found
      a = 1*n array containing all the lower ends of the brackets
      where n is the number of roots
      b = 1*n array containing all the lower ends of the brackets
      where n is the number of roots
      tol = absolute error tolerance with which to find the root;
      Iteration terminates when the root is known to within +/- tol
   %Outputs:
   % sol = 1*n array of of roots
   \% i = 1*n array of the number of iterations required to find the nth
   % root
   %
      err =
   %
   %Usage:
   % [r, i, err] = bisect(@(x) x.^2 - 4, 1, 3, 5e-9) \rightarrow returns the
   % approximation to root of x^2 - 4 = 0 within [1, 3], the number of
   % iterations required to find the root and the final absolute error
   % check if all intervals are correctly defined
   assert(isequal(size(a), size(b)),...
       "Must be an equal number of upper and lower bounds");
```

```
% check whether f changes sign
   assert(all(sign(f(a)) ~= sign(f(b))),...
       'f(a) and f(b) should have opposite sign');
   % intialise variables
   % iteration counter
   i = zeros(size(a));
   % current solution estimate
   sol = (a + b)/2;
   % previous solution estimate
   sol_old = Inf;
   % absolute error
   err = Inf;
   withinTol = zeros(size(a));
   % bisection algorithm:
   \% at each iteration, find the half-interval that contains a sign change
   % and relabel the endpoints appropriately
   while any(~withinTol)
      i(~withinTol) = i(~withinTol) + 1;
       sol_old = sol;
       mid = (a + b)/2;
       % mid point is a root
       exactRoot = f(mid) == 0;
       sol(exactRoot) = mid(exactRoot);
       err(exactRoot) = 0;
       withinTol(exactRoot) = true;
       \% solution is in first half of interval and mid point not a root
       firstHalf = (sign(f(a)) ~= sign(f(mid))) & ~exactRoot;
       b(firstHalf) = mid(firstHalf);
       \ensuremath{\text{\%}} solution is in second half of interval and mid point not a root
       secondHalf = (sign(f(a)) == sign(f(mid))) & ~exactRoot;
       a(secondHalf) = mid(secondHalf);
       % update solutions and errors values that aren't within tolerance
       sol(~withinTol) = (a(~withinTol) + b(~withinTol))/2;
       err(~withinTol) = abs(sol(~withinTol) - sol_old(~withinTol));
       withinTol(err < tol) = true;</pre>
   end
end
```

(i) Solutions to  $f(x) = x^4 - e^{-x}\cos(x) = 0$   $x \in [-2\pi, 2\pi]$ .

Listing 7: ../src/q1/Q1b\_i\_funcRoots.m

```
f = @(x) x.^4 - exp(-x).*cos(x);
a = [-1.5 0.5];
b = [-1 1];
[r, i, err] = bisectRoot(f, a, b, [5e-8 5e-9])
```

Note the two different tolerances since one root is an order of magnitude larger so requires one less decimal place of tolerance to be accurate to 8 significant figures.

$$\begin{array}{c|cccc} [a,b] & \text{Root} & \# \text{ Iterations} \\ \hline [-1.5,-1] & -1.0843597 & 23 \\ [0.5,1] & 0.76221107 & 26 \\ \end{array}$$

(ii) Solutions to  $f(x) = \frac{x^3}{\sin(x)} - 1 = 0$   $x \in [-2\pi, 2\pi]$ .

Listing 8: ../src/q1/Q1b\_ii\_funcRoots.m

```
f = @(x) (x.^3)./sin(x) - 1;
a = [-1 0.5];
b = [-0.5 1];
[r, i, err] = bisectRoot(f, a, b, 5e-9)
```

$$\begin{array}{c|cccc} [a,b] & \text{Root} & \# \text{ Iterations} \\ \hline [-1,-0.5] & -0.92862631 & 26 \\ [0.5,1] & 0.92862631 & 26 \\ \end{array}$$

(iii) Solutions to  $f(x) = \cot(x) - \frac{25}{25x-1} = 0$   $x \in [-2\pi, 2\pi]$ .

Listing 9: ../src/q1/Q1b\_iii\_funcRoots.m

```
f = @(x) cot(x) - 25./(25*x - 1);

a = [-5 -1 4];

b = [-4 -0.1 5];

[r, i, err] = bisectRoot(f, a, b, [5e-8 5e-9 5e-8])
```

| [a,b]      | Root        | # Iterations |
|------------|-------------|--------------|
| [-5, -4]   | -4.4953722  | 24           |
| [-1, -0.1] | -0.47773376 | 27           |
| [4, 5]     | 4.4914097   | 24           |

(iv) Solutions to  $f(x) = 4e^{-x^2/5} - \cos(5x) - 2 = 0$   $x \in [-2\pi, 2\pi]$ .

Listing 10: ../src/q1/Q1b\_iv\_funcRoots.m

```
f = @(x) 4*exp(-x.^2/5) - cos(5*x) - 2;

a = [-2.5 -1.5 -1.25 1 1.25 2];

b = [-2 -1.25 -1 1.25 1.5 2.5];

[r, i, err] = bisectRoot(f, a, b, 5e-8)
```

| [a,b]         | Root       | # Iterations |

| [-1.5, -1.25] | -1.4255432 | 22           |
| [-1.25, -1]   | -1.2145933 | 22           |
| [1, 1.25]     | 1.2145933  | 22           |
| [1.25, 1.5]   | 1.4255432  | 22           |
| [2, 2.5]      | 2.1222382  | 23           |

(c) The iterative scheme we asked to implement is called Steffensen's method. This is implemented in the steffensenRoot function.

Listing 11: ../src/q1/steffensenRoot.m

```
function [r, n, err] = steffensenRoot(f, x0, tol, nMax)
%steffensenRoot uses Steffensen's method to find roots of f(x)
```

```
% based on an initial guess x0
%Inputs:
\% f = function handle to function whose root is to be found
\% x0 = initial guess of the root to begin iteration at
% tol = absolute error tolerance with which to find the root
\% iteration terminates when the root is known to within +/- tol
% nMax = the maximum number of iteration to quit after. Prevents an
% infinite loop if the iterations do not converge
%
%Outputs:
% r = the approximate root of f(x)=0
% n = the number of interations
% err = 1*n vector of the absolute error after each interation
%Usage:
% [r, n, err] = steffensenRoot(@(x) exp(-x) -x, 0, 5e-9, 50) \rightarrow
\% returns the approximate roo of x^-x - x = 0 after n iterations and
% = 1000 err the absolute error after each iteration
% set initial guess as first root
xn = x0;
%iteration counter
n = 0;
% preallocate error array
err = Inf(1, nMax);
while all(err > tol) && n < nMax</pre>
   n = n + 1;
   x01d = xn;
   % Calculate f(xn) to avoid repeat computation
   fn = f(xn);
   % Calculate next interation
   xn = xn - fn*(f(xn + fn)/fn - 1)^-1;
   err(n) = abs(xn - x01d);
end
% remove any unused preallocated element in error array
err(isinf(err)) = [];
% check if solution converged
assert(err(end) < tol, "No convergence")</pre>
r = xn;
```

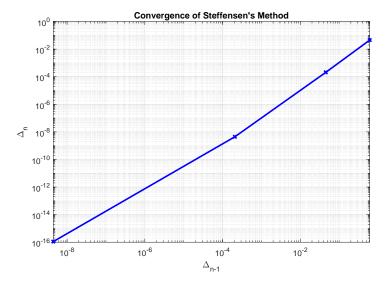

The following uses this function to find the root of  $e^{-x} - x = 0$  and calculate the convergence.

Listing 12: ../src/q1/Q1c\_errorConvergance.m

```
f = @(x) exp(-x) - x;
[r, n, e] = steffensenRoot(f, 0, 5e-13, 50);
%% Generate plot of convergence
loglog(e(1:end-1),e(2:end), "bx-", "LineWidth", 2)
title("Convergence of Steffensen's Method")
xlabel('\Delta_{n-1}');
ylabel('\Delta_{n}');
xlim([e(end - 1) e(1)]);
grid on;
%% Find order of congerence
```

```
polyfit(log(e(1:end-1)), log(e(2:end)), 1)
```

After 5 iterations the root x = 0.567143290410 is accurate to 12 decimal places.

The graph shows a straight which shows error  $\propto \Delta_{n-1}^q$ , where q is the gradient of the line. Using the MATLAB function polyfit the gradient of the above graph as 1.8 which is approximately 2 so Steffensen's method is second order.

(d) The first step in creating a cobweb plot is to implement a fixed point iteration scheme.

Listing 13: ../src/q1/fixedPointRoot.m

```
function xn = fixedPointRoot(g, x0, nMax)
   % fixedPointRoot Iteration to find solutions of x = g(x)
   %
   %Inputs:
   % g = function handle to find the solutions of x = g(x)
   % x0 = first term of the iteration
   % nMax = the maximum number of iteration to quit after
   %Output:
   % xn = the iteraterative sequence
   %Usage:
   % xn = fixedPointRoot(@(x) cos(x), 0.75, 100) \rightarrow looks for a
      root of the equation x - cos(x) = 0, starting with an inital guess
      of 0.75.
   % number of iterations
   % preallocated sequence array and set initial guess as first term
   xn = NaN(1, nMax);
   xn(1) = x0;
   % set initial error
   err = Inf;
   % iterate x -> g(x)
   while n < nMax
       n = n + 1;
```

```
xn(n + 1) = g(xn(n));
err = abs(xn(n + 1) - xn(n));
end

% remove any unused elements of the preallocated array
xn(isnan(xn)) = [];

fprintf('\nAfter %d steps root is %-20.14g\n', n, xn(end));
fprintf('Final absolute error is %g\n\n', err);
end
```

Then the cobwebDiagram function can display the results of the fixed point iteration.

Listing 14: ../src/q1/cobwebDiagram.m

```
function cobwebDiagram(g, x0, n, a, b)
   %cobwebDiagram Creates cobweb diagram for x = g(x) in interval [a,b]
   %
   %Inputs:
   % g = function handle for g(x)
   \% x0 = initial guess to start iteration
   \% nMax = number of iterations to complete
   % a = lower end of interval [a,b] to plot cobweb diagram over
   \% b = upper end of interval [a,b] to plot cobweb diagram over
   % cobwebDiagram(Q(x) (x.^5 + 3)/5, 1, 10, 0, 1.5) -> produces a
   % cobweb diagram of x = (x^5 + 3)/5 based on an initial guess of 10
   \% and 10 iterations. This is shown over the interval [0,1.5].
   %% get fixed point iteration sequence
   xn = fixedPointRoot(g, x0, n);
   %% generate cobweb diagram
   % get values for the line y = x and y = g(x)
   x = linspace(a, b);
   y = g(x);
   y(isinf(y)) = NaN;
   y(y \sim real(y)) = NaN;
   % set up figure
   hold on;
   grid on;
   set(gca, "DefaultLineLineWidth", 2);
   title("Cobweb plot for fixed point iteration");
   xlabel("x");
   ylabel("y")
   xlim([a b])
   ylim([min(x(1), y(1)) max(x(end), y(end))]);
   % plot lines y = x and y = g(x)
   plot(x, x, "r-", "DisplayName", "y = x");
   plot(x, y, "k-", "DisplayName", "y = g(x)");
   legend("AutoUpdate", "off");
   % plot the steps
   plot([xn(1) xn(1)], [0 xn(2)], 'm-');
   for i=1:length(xn) - 2
      plot([xn(i) xn(i + 1)], [xn(i + 1) xn(i + 1)], 'm-');
```

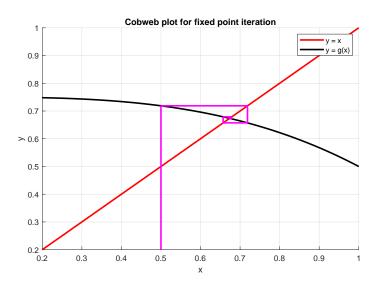

```
plot([xn(i + 1) xn(i + 1)], [xn(i + 1) xn(i + 2)], 'm-');
end
end
```

The function requires user inputs of the iteration function g(x), the initial guess  $x_0$ , the number of iterations and the interval to display on the x-axis (which should contain the root). The reason to user has to enter the range to display on the x-axis is because in the case of divergence the estimate of the root can shoot off to very large value which when plotted make previous iteration so small that the plot doesn't show anything meaningful.

The first test I did was to ensure it could produce a cobweb diagram. For this I set  $g(x) = \frac{3-x^3}{4}$  with an initial guess of  $\frac{1}{2}$ .

Listing 15: ../src/q1/Q1d\_cobweb\_example.m

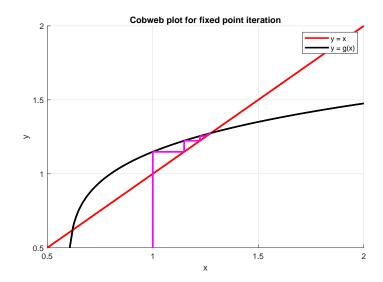

cobwebDiagram(@(x) (3 - x.^3)/4, 0.5, 10, 0.2, 1)

Next I tested producing a staircase diagram, so I set  $g(x) = \sqrt[5]{5x-3}$  with an initial guess of 1.

Listing 16: ../src/q1/Q1d\_staircase\_example.m

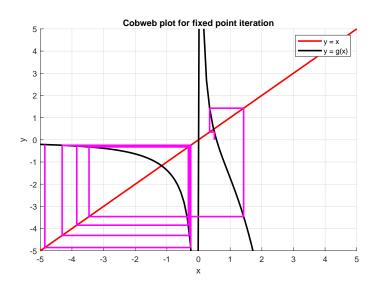

cobwebDiagram(@(x) (5\*x - 3).^0.2, 1, 10, 0.5, 2)

Since the function should also be able to handle iterations that don't converge, I tried  $g(x) = \frac{1-xe^x}{x}$  with an initial guess of  $\frac{1}{2}$ .

Listing 17: ../src/q1/Q1d\_divergance\_example.m

cobwebDiagram(@(x) (1 - x.\*exp(x))./x, 0.5, 10, -5, 5)

This cobweb diagram shows how the gradient at the root is too steep which means the iteration fails to converge. This is also shown by that fact that the approximate absolute error at the final step is still  $\sim 4.6$ . I also tested it with a number of other function both converge and diverge however these have been omitted from the report to save space.

### Question 2: Numerical integration and differentiation

(a) (i) The first expression is Simpson's 3/8 rule and the second is Milne's rule. Simpson's 3/8 rule can be implemented as follows.

```
function simpQuad = simpson38(f, a, b)
   %simpson38 approximates integral of f(x) over interval [a,b] by using
   %Simpson's 3/8 rule
   %Inputs:
   % f = function handle of the integrand f(x)
   % a = lower bound of the interval
   % b = upper bound of the interval
   %
   %Outputs:
   % simpQuad = approximate quadrature
   %
   %Usage:
   \% quad = simpson38(@(x) x^2, 0, 0.5) -> returns the approximate
   % intergal of x^2 in the interval [0, 0.5]
   simpQuad = (b - a)/8 .* (f(a) + 3*f((2*a + b)/3) + 3*f((a + 2*b)/3)...
       + f(b));
```

And similarly Milne's rule can be implemented.

Listing 19: ../src/q2/milne.m

However to use the composite version the integral must be broken down into smaller intervals. For example breaking the integral into n intervals gives  $\int_a^b f(x)dx = \int_a^{x_1} f(x)dx + \int_{x_1}^{x_2} f(x)dx + \cdots + \int_{x_{n-1}}^b f(x)dx$  where  $x_i = a + i \cdot \frac{b-a}{n}$ . Then each of these smaller integrals can be calculated using either of the methods. The compositeQuad function breaks down the integral into smaller intervals before using a Newton-Coutes method of choice to approximate the integral.

Listing 20: ../src/q2/compositeQuad.m

```
% interval to integrate over
% a = lower bound of the interval
% b = upper bound of the interval
% tol = desired absolute error tolerance
%Outputs:
% compQuad = vector of the sucessive approximates of the
\% quadrature where the final entry is the final approximate
\% h = vector of the step size used at each approximation
% err = vector of the absolute error at each approximation
%Usage:
% compositeQuad(Q(x) \exp(x), Q(f, a, b) (b - a)/2 .*(f(a) + f(b)),...
\% 0, 1, 5e-4) -> Estimates the quadrature of e^x in the interval
% [0,1] using the trapezium rule to 3 decimal places
\% max number of iterations to prevent infinite loop
nMax = 25;
% iteration counter
n = 1;
% number of subintervals
N = 2;
% preallocate vectors for the error, quadrature and step size
err = inf(1, nMax);
compQuad = NaN(1, nMax);
h = NaN(1, nMax);
while all(err > tol) && n < nMax</pre>
   % generate step size
   h(n) = (b - a)/N;
   % calculate lower bounds
   lowerBounds = a + h(n).*[0:N-1];
   \% calculate upper bounds
   upperBounds = a + h(n).*[1:N];
   % calculate quadrature using given Newton-coutes method
   compQuad(n) = sum(i(f, lowerBounds, upperBounds));
   % calculate absolute error
       err(n) = abs(compQuad(n) - compQuad(n - 1));
       % prevents error when calculating first error term as no
       % previous approximation to compare againsy
       err(n) = inf;
   end
   n = n + 1;
   N = N * 2;
% removed any used preallocation
err(isinf(err)) = [];
compQuad(isnan(compQuad)) = [];
h(isnan(h)) = [];
```

For an example both methods can be used to evaluate  $\int_0^5 e^x - x dx$  to 6 decimal places as follows.

Listing 21: ../src/q2/Q2ai\_exampleIntegration.m

```
f = @(x) exp(x) - x;
a = 0;
b = 5;
tol = 5e-7;
% using Simpson's 3/8 rule
compositeQuad(f, @simpson38, a, b, tol)
% using Milne's rule
compositeQuad(f, @milne, a, b, tol)
```

Both give the answer to the example as 134.913159.

(ii) The order of a Newton-Cotes method is measured with respect to h (the size of subintervals).

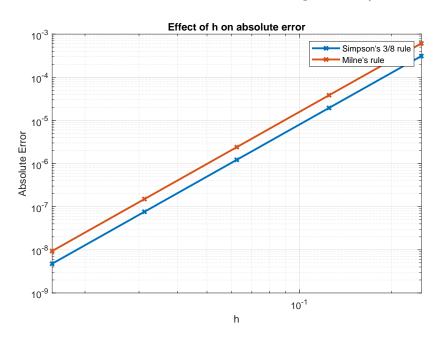

Figure 1: Error convergance of composite Simpson's 3/8 rule and composite Milne's rule. Generated using Listing 31.

Figure 1 shows both method produce a straight line which shows error  $\propto h^q$  where q is the gradient. The polyfits function shows both line have a gradient of 4 which means both composite Simpson's 3/8 rule and composite Milne's rule are 4th order.

The accuracy is the highest order polynomial that the method can integrate exactly. So to find the degree of accuracy of each method test it on a variety of polynomials of increasing order and see if it can integrate the polynomial exactly.

|                   | Exact Value   | Simpon's 3/8 Rule                      | Milne's Rule                           |
|-------------------|---------------|--|--|
| $\int_0^1 x \ dx$ |               | 0.5                                    | 0.5                                    |
| $\int_0^1 x^2 dx$ | $\frac{1}{3}$ | 0.333333333333333333333333333333333333 | 0.333333333333333333333333333333333333 |
| $\int_0^1 x^3 dx$ | $\frac{1}{4}$ | 0.25                                   | 0.25                                   |
| $\int_0^1 x^4 dx$ | $\frac{1}{5}$ | 0.203703703703704                      | 0.1927083333333333                     |

This shows that both methods are of degree of accuracy 3 as they can both exact integrate cubics but not quartics.

Whilst both methods are fourth order Simpson's 3/8 rule has a lower error term so is slightly better as it is more accurate. This is shown in page 14 as the absolute error for Simpson's 3/8

rule is always less.

(b) (i) To find the order of the rounding and truncation error the absolute error is plotted against h.

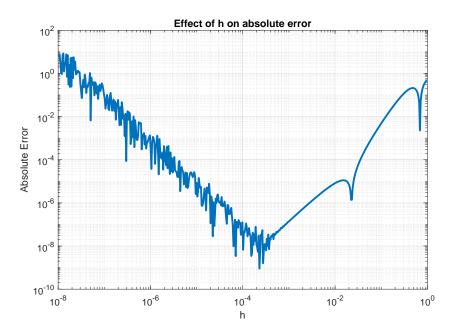

Figure 2: Plot generated by Listing 32

The gradient of the two sections of the graph shows the order of the rounding and truncation error. The rounding error is shown by the jagged first half which has a gradient of -2 which shows the order of the rounding error is  $\mathcal{O}(h^{-2})$ . The second half of the graph shows the truncation error. This has a gradient of 2 which shows the truncation error is  $\mathcal{O}(h^2)$ .

(ii) The error is comprised of the truncation and rounding error. To find the truncation error of

$$f''(x) \approx \frac{2f(x) - 5f(x+h) + 4f(x+2h) - f(x+3h)}{h^2},\tag{1}$$

consider the following taylor expansions

$$f(x+h) = f(x) + hf'(x) + \frac{h^2}{2}f''(x) + \frac{h^3}{6}f^{(3)}(x) + \frac{h^4}{24}f^{(4)}(x) + \cdots,$$
 (2)

$$f(x+2h) = f(x) + 2hf'(x) + \frac{4h^2}{2}f''(x) + \frac{8h^3}{6}f^{(3)}(x) + \frac{16h^4}{24}f^{(4)}(x) + \cdots,$$
 (3)

$$f(x+3h) = f(x) + 3hf'(x) + \frac{9h^2}{2}f''(x) + \frac{27h^3}{6}f^{(3)}(x) + \frac{81h^4}{24}f^{(4)}(x) + \cdots$$
 (4)

Substituting (2), (3), (4) into (1) gives

$$f''(x) \approx \frac{h^2 f''(x) + \frac{-11}{12} h^4 f^{(4)}(x) + \mathcal{O}(h^5)}{h^2}$$
 (5)

$$= f''(x) - \frac{11}{12}h^2f^{(4)}(x) + \mathcal{O}(h^3), \tag{6}$$

so the truncation error is  $\frac{11}{12}h^2f^{(4)}(x) + \mathcal{O}(h^3)$ .

To find the rounding error assume h is small and can be stored exactly. So the rounding error in storing f(x), f(x+h), f(x+2h) and f(x+3h) is  $|f(x)|\epsilon$ , where  $\epsilon$  is the floating point

relative accuracy,  $2 \times 10^{-16}$ . This means the total rounding error is  $\frac{12|f(x)|\epsilon}{h^2}$ . So the total error is given by

error 
$$\approx \frac{11}{12}h^2 f^{(4)}(x) + \frac{12|f(x)|\epsilon}{h^2}$$
. (7)

We want to minimise the error so

$$\frac{d}{dt}\operatorname{error} \approx \frac{22}{12}hf^{(4)}(x) - \frac{24|f(x)|\epsilon}{h^3} = 0.$$
(8)

Approximating  $f(x) \approx f^{(4)}(x)$  gives

$$\frac{22}{12}h - \frac{24\epsilon}{h^3} = 0, (9)$$

so the h which minimises the error is

$$h = \sqrt[4]{\frac{144}{11}\epsilon}. (10)$$

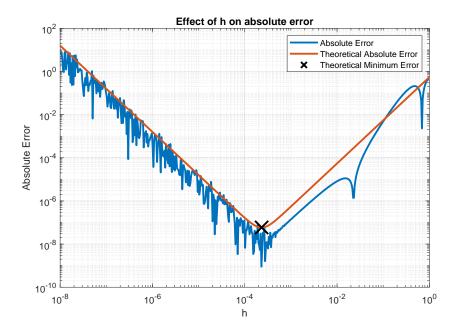

Figure 3: Plot produced using Listing 33

The algebraic expression has the same gradient however it is offset. This is because it assumes that h can be stored exactly and because it assumes  $f(x) \approx f^{(4)}(x)$ . However the value of h that minimises error lines up correctly.

## Question 3: Numerical solution of ODEs

Listing 22: ../src/q3/rhsProjectile.m

### (b) (i) Forward Euler

Listing 23: ../src/q3/forwardEulerProjectile.m

```
function [t, y] = forwardEulerProjectile(rhs, tSpan, y0, g, mu, n)
   %forwardEulerProjectile solves the projectiles motion using forward
   %euler
   %
   %Inputs:
   % rhs = function handle for rhs of ode returning a column vector
   % [x,y,u,v]
   % tSpan = vector [a,b] which is the time interval to solve ODE over
   % y0 = 1*4 vector of initial conditions [x0,y0,u0,v0]
   % g = value of the acceleration due to gravity
   % mu = value of the drag parameter
   \% n = the number of steps to split integration over
   %
   %Outputs:
   \% t = column vector of solution times
   \mbox{\%} \quad \mbox{y = matrix of solutions} where each row is the values of each of the
   \mbox{\ensuremath{\%}} varibles at the corisponding value of t in the same fashion as
   % ode45
   %Usage:
   % [t,y]=forwardEulerProjectile(@rhsProjectile, [0 5],...
   \% [0 0 31 21]', 9.81, 2.79e-2, 100) -> Solves the projectile ODE from
      t=1 to 5 with 100 steps
   t = linspace(tSpan(1), tSpan(end), n + 1);
   % preallocate solution matix
   y = zeros(numel(t), numel(y0));
   % calculate step size
   h = (tSpan(end) - tSpan(1))/n;
   % parse parameter values to RHS function
   f = @(t,y) rhs(t, y, g, mu);
   % set initial conditions
   y(1,:) = y0';
   % forward euler method
   for i = 1:n
      y(i + 1,:) = y(i,:) + h * f(t(i), y(i,:))';
    end
```

#### (ii) 4th-order Runge-Kutta

Listing 24: ../src/q3/rk4Projectile.m

```
% n = the number of steps to split integration over
   %Outputs:
   % t = column vector of solution times
   % y = matrix of solutions where each row is the values of each of the
   \mbox{\ensuremath{\mbox{\%}}} varibles at the corisponding value of t in the same fashion as
   %Usage:
   % [t,y]=rk4Projectile(@rhsProjectile, [0 5],...
   \% [0 0 31 21]', 9.81, 2.79e-2, 100) -> Solves the projectile ODE from
   % t=1 to 5 with 100 steps
   t = linspace(tSpan(1), tSpan(end), n + 1);
   % preallocate solution matix
   y = zeros(numel(t), numel(y0));
   % calculate step size
   h = (tSpan(end) - tSpan(1))/n;
   % parse parameter values to RHS function
   f = Q(t,y) rhs(t, y, g, mu);
   % set initial conditions
   y(1,:) = y0';
   for i=1:n
       m1 = f(t(i), y(i,:))';
       m2 = f(t(i) + h/2, y(i,:) + m1 * h/2)';
       m3 = f(t(i) + h/2, y(i,:) + m2 *h/2)';
       m4 = f(t(i) + h, y(i,:) + m3 *h)';
       y(i + 1,:) = y(i,:) + (h/6)*(m1 + 2*m2 +2*m3 +m4);
   end
end
```

(iii) ode45

Listing 25: ../src/q3/ode45projectile.m

[t, y] = ode45(@(t, y) rhsProjectile(t, y, g, mu), tSpan, y0');

(c) Solving the ODE using the three different solvers gives the following trajectories.

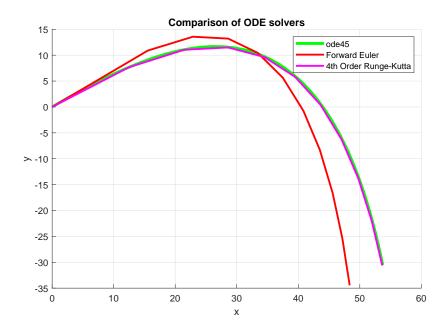

Figure 4: Comparision of the three different solutions. Plot produced using Listing 34

## (d) Error compared to ode45.

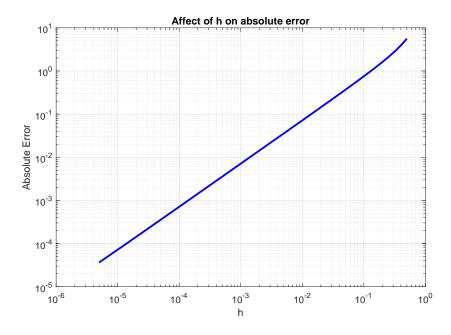

Figure 5: Generated using Listing 35

The order of global truncation error can be given by the gradient in the limit as  $h \to 0$ . In this case the gradient is 1 so the global truncation error is  $\mathcal{O}(h)$ .

(e) To find when the projectile crosses the x-axis first an event function is created.

Listing 26: ../src/q3/xaxisEvent.m

```
function [value, isTerminal, direction] = xaxisEvent(t, y)
% halt when the ball reaches xaxis ie. y = 0
```

```
value = y(2);

% end integration
isTerminal = 1;

% ball should be falling
direction = -1;
end
```

Then solve the ODE with the added event function.

Listing 27: ../src/q3/Q3e\_eventDetection.m

```
%% setup parameters
tSpan = [0 5];
v0 = 38;
theta0 = deg2rad(35);
g = 9.81;
mu = 2.79e-2;
h = 0.5;
n = (tSpan(end) - tSpan(1))/h;
%initial conditions
y0 = [0 \ 0 \ v0*cos(theta0) \ v0*sin(theta0)]';
%% solve ODE
options = odeset("Events", @xaxisEvent);
[t, y, te, ye , ie] = ode45(@(t, y) rhsProjectile(t, y, g, mu), tSpan,...
   y0, options);
%% display result
fprintf("Projectile first crosses x axis at %.13f\n", te)
```

This gives that the projectile first passes through the x-axis when t = 3.038777368718

(f) An equivalent formulation to this problem is to consider the angles  $\theta_0$  required so that when a particle is fired from (-40,0) it lands through the origin (0,0). This can be visualized by plotting the landing x coordinate against  $\theta_0$  as shown in Figure 6.

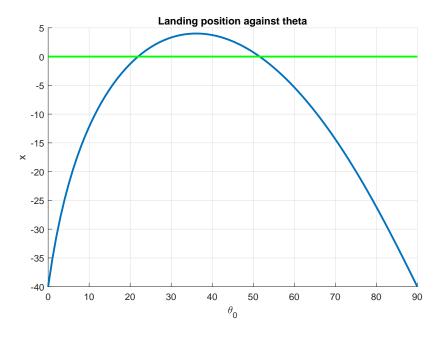

Figure 6: Generated using Listing 36

This shows the problem can be reduced to a root finding problem. This can be done using the bisection method already implemented in Listing 6 or Stephen's method implemented in Listing 11. The two values of  $\theta_0$  can be bracketed by the intervals [20, 25] and [50, 55]. First a function,  $x(\theta_0)$ , that returns just the landing position given a  $\theta_0$  needs to be created.

Listing 28: ../src/q3/landingPosition.m

```
function x = landingPosition(theta)
   %% setup parameters
   tSpan = [0 5];
   v0 = 38;
   g = 9.81;
   mu = 2.79e-2;
   theta0 = deg2rad(theta);
   %% solve ODE for a range of theta
   %set event detection
   options = odeset("Events", @xaxisEvent);
   \ensuremath{\text{\%}} calculate initial conditions for a given theta
   y0 = [-40 \ 0 \ v0*cos(theta0) \ v0*sin(theta0)]';
   [t, y, te, ye, ie] = ode45(@(t, y) rhsProjectile(t, y, g, mu), tSpan,...
   y0, options);
   x = ye(1);
end
```

Then using the bisection method the roots of  $x(\theta_0) = 0$  can be found.

```
Listing 29: ../src/q3/Q3f_thetaSolution.m
```

```
bisectRoot(@landingPosition, 20,25, 5e-20)
bisectRoot(@landingPosition, 50,55, 5e-20)
```

This gives  $\theta_0 = 21.9185709$  or  $\theta_0 = 51.567361$  as solutions to the initial angle so that the projectile crosses the x-axis 40m away.

## Appendix A Additional Code for Question 1

Listing 30: ../src/q1/pltFunc.m

```
function pltFunc(f, domain, discontLim)
   %pltFunc plots function f between values of xLim removing any values
   \mbox{\ensuremath{\mbox{\%}}} that are greater than discont
Lim to prevent MATLAB plotting
   \% discontinuous functions as continous and plots a line of x = 0 to
   % help make any zeros clear
   % Input:
   % f = function handle to plot
      domain = 1x2 vector containing the lower and upper bound of the
      discountLim = absolute values of the function greater than this are
      changed to NaN. Setting to inf will plot all values of the function
   % Usage:
   % pltFunc(@(x) 1./x, [-10 10], 5) \rightarrow Plots 1/x between -10 and 10
   % changing the values where |1/x| > 5 to NaN
   % Check xLim is the correct dimensions
   assert(isequal(size(domain), [1 2]), "domain must be a 1x2 vector")
   %% Generate values to plot
   x = linspace(domain(1), domain(2));
   y = f(x);
   % Remove large values of y to prevent MATLAB plotting discontinuous
   % functions as continuous
