#### EMAT20920: Numerical Methods in MATLAB

# COURSEWORK ASSESSMENT Jake Bowhay (UP19056)

All figures in this report have been saved using saveFigPDF function as it automatically resizes the paper to the correct size.

### Question 1: Root-finding

(a) To find how many solutions each equation has in the given domain I will rearrange all the equations to be equal to zero and then looks for the zeros of the rearranged equations. As a corollary to the intermediate value theorem, if a function is continuous and changes sign in a bracket then that bracket must contain a zero. So I will plot each of the rearranged equation and I look for appropriate brackets. I will use the pltFunc function to plot the functions as it removes values outside a defined limit which prevents MATLAB plotting discontinuous functions as continuous. The limits can then be changed using the property explorer to give a more useful plot.

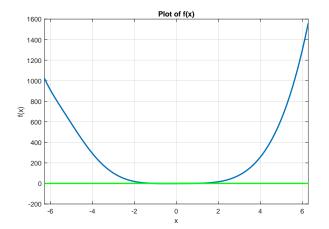

```
% Check xLim is the correct dimensions
assert(isequal(size(domain), [1 2]), "domain must be a 1x2 vector")

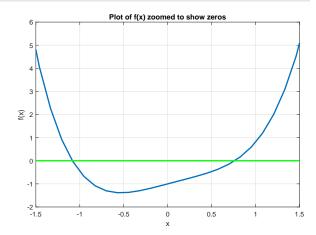

%% Generate values to plot
x = linspace(domain(1), domain(2));
y = f(x);

% Remove large values of y to prevent MATLAB plotting discontinuous
% functions as continuous
y(abs(y)>discontLim) = NaN;

%% Plot function and line x = 0
plot(x, y, [min(x) max(x)], [0 0], "g-", "LineWidth", 2);
xlabel("x");
ylabel("f(x)");
xlim(domain);
title("Plot of f(x)");
grid on;
end
```

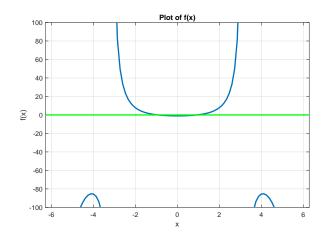

(i) Rearranging  $x^4 = e^{-x} \cos(x)$  gives  $f(x) = x^4 - e^{-x} \cos(x)$ .  $f = @(x) x^4 - \exp(-x).*\cos(x)$ ; pltFunc(f, [-2\*pi 2\*pi], inf);

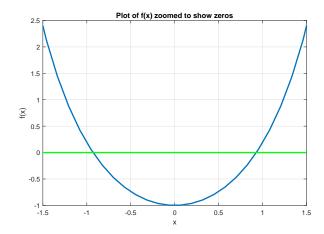

The second zoomed in plot shows there are two zeros in the given domain. The first zero can be bracketed by the interval [-1.5, -1] as f(-1.5) = 4.7455 and f(-1) = -0.4687 so since the function is continuous and there is a change of sign this bracket must contain a zero. Like wise the second root can be bracketed by the interval [0.5, 1] as f(0.5) = -0.4698 and f(1) = 0.8012.

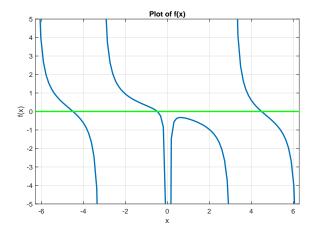

(ii) Setting 
$$f(x) = \frac{x^3}{\sin(x)} - 1$$
.  
 $f = @(x) (x.^3)./\sin(x) - 1$ ;  
 $pltFunc(f, [-2*pi 2*pi], 500)$ ;

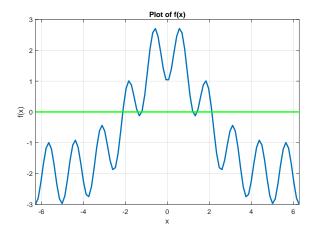

The second plot show there are two roots. The first root can be bracketed by the interval [-1, -0.5] as f(-1) = 0.1884 and f(-0.5) = -0.7393 and f(x) is continuous in this bracket. Likewise, the second root can be bracketed by the interval [0.5, 1] as f(0.5) = -0.7393 and f(1) = 0.1884.

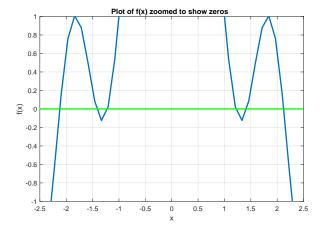

(iii) Rearranging 
$$\cot(x) = \frac{25}{25x-1}$$
 gives  $f(x) = \cot(x) - \frac{25}{25x-1}$ .  
f = @(x)  $\cot(x)$  - 25./(25\*x - 1);  
pltFunc(f, [-2\*pi 2\*pi], 30);

The plot shows that the equation has three solutions. The first can be bracketed by the interval [-5, -4] as f(-5) = 0.4942 and f(-4) = -0.6162. The second solution can be bracketed by the interval [-1, -0.1] as f(-1) = 0.3194 and f(-0.1) = -2.8238. The third solution can be bracketed by the interval [4, 5] as f(4) = 0.6112 and f(5) = -0.4974. f(x) is continuous in each of the bracketing intervals.

(iv) Rearranging 
$$4e^{-x^2/5} = \cos(5x) + 2$$
 gives  $f(x) = 4e^{-x^2/5} - \cos(5x) - 2$ .  
f = @(x) 4\*exp(-x.^2/5) - cos(5\*x) - 2;  
pltFunc(f, [-2\*pi 2\*pi], inf);

The second plot shows that the equation has 6 solutions. The bracketing intervals are shown in the table below.

[a,b]	f(a)	f(b)
[-2.5, -2]	-1.8518	0.6364
[-1.5, -1.25]	0.2039	-0.0730
[-1.25, -1]	-0.0730	0.9913
[1, 1.25]	0.9913	-0.0730
[1.25, 1.5]	-0.0730	0.2039
[2, 2.5]	0.6364	-1.8518

(b) The bisection method is used by calling the the bisectRoot function.

```
function [sol, i, err] = bisectRoot(f, a, b, tol)
   %bisectRoot Use the bisection method to find roots of the function f
   % bracketed within the intervals [a, b].
   %Inputs:
   \% \hspace{0.4cm} f = function handle to function whose root is to be found
   \% a = 1*n array containing all the lower ends of the brackets
   % where n is the number of roots
   \% b = 1*n array containing all the lower ends of the brackets
   % where n is the number of roots
   % tol = absolute error tolerance with which to find the root;
   \% Iteration terminates when the root is known to within +/- tol
   %
   %Outputs:
   % sol = 1*n array of of roots
   \% i = 1*n array of the number of iterations required to find the nth
   %
      err =
   %
   %Usage:
   % [r, i, err] = bisect(@(x) x.^2 - 4, 1, 3, 5e-9) \rightarrow returns the
   % approximation to root of x^2 - 4 = 0 within [1, 3], the number of
   \% iterations required to find the root and the final absolute error
   % check if all intervals are correctly defined
   assert(isequal(size(a), size(b)),...
       "Must be an equal number of upper and lower bounds");
```

```
% check whether f changes sign
   assert(all(sign(f(a)) ~= sign(f(b))),...
       'f(a) and f(b) should have opposite sign');
   % intialise variables
   % iteration counter
   i = zeros(size(a));
   % current solution estimate
   sol = (a + b)/2;
   % previous solution estimate
   sol_old = Inf;
   % absolute error
   err = Inf;
   withinTol = zeros(size(a));
   % bisection algorithm:
   \% at each iteration, find the half-interval that contains a sign change
   % and relabel the endpoints appropriately
   while any(~withinTol)
      i(~withinTol) = i(~withinTol) + 1;
       sol_old = sol;
       mid = (a + b)/2;
       % mid point is a root
       exactRoot = f(mid) == 0;
       sol(exactRoot) = mid(exactRoot);
       err(exactRoot) = 0;
       withinTol(exactRoot) = true;
       \ensuremath{\text{\%}} solution is in first half of interval and mid point not a root
       firstHalf = (sign(f(a)) ~= sign(f(mid))) & ~exactRoot;
       b(firstHalf) = mid(firstHalf);
       \ensuremath{\text{\%}} solution is in second half of interval and mid point not a root
       secondHalf = (sign(f(a)) == sign(f(mid))) & ~exactRoot;
       a(secondHalf) = mid(secondHalf);
       \% update solutions and errors values that aren't within tolerance
       sol(~withinTol) = (a(~withinTol) + b(~withinTol))/2;
       err(~withinTol) = abs(sol(~withinTol) - sol_old(~withinTol));
       withinTol(err < tol) = true;</pre>
   end
end
```

```
(i) Solutions to f(x) = x^4 - e^{-x}\cos(x) = 0 x \in [-2\pi, 2\pi].

f = @(x) x^4 - \exp(-x).*\cos(x);

a = [-1.5 0.5];

b = [-1 1];

[r, i, err] = bisectRoot(f, a, b, [5e-8 5e-9])
```

Note the two different tolerances since one root is an order of magnitude larger so requires one less decimal place of accuracy to be accurate to 8 significant figures.

[a,b]	Root	# Iterations
[-1.5, -1]	-1.0843597	23
[0.5, 1]	0.76221107	26

(ii) Solutions to  $f(x) = \frac{x^3}{\sin(x)} - 1 = 0$   $x \in [-2\pi, 2\pi]$ .

```
f = @(x) (x.^3)./sin(x) - 1;
a = [-1 0.5];
b = [-0.5 1];
[r, i, err] = bisectRoot(f, a, b, 5e-9)
```

$$\begin{array}{c|cccc} [a,b] & \text{Root} & \# \text{ Iterations} \\ \hline [-1,-0.5] & -0.92862631 & 26 \\ \hline [0.5,1] & 0.92862631 & 26 \\ \end{array}$$

(iii) Solutions to  $f(x) = \cot(x) - \frac{25}{25x-1} = 0$   $x \in [-2\pi, 2\pi]$ .

```
f = @(x) cot(x) - 25./(25*x - 1);

a = [-5 -1 4];

b = [-4 -0.1 5];

[r, i, err] = bisectRoot(f, a, b, [5e-8 5e-9 5e-8])
```

$$[a,b]$$

(iv) Solutions to 
$$f(x) = 4e^{-x^2/5} - \cos(5x) - 2 = 0$$
  $x \in [-2\pi, 2\pi]$ .  
 $f = @(x) 4*exp(-x.^2/5) - \cos(5*x) - 2;$   
 $a = [-2.5 -1.5 -1.25 \ 1 \ 1.25 \ 2];$   
 $b = [-2 -1.25 -1 \ 1.25 \ 1.5 \ 2.5];$   
 $[r, i, err] = bisectRoot(f, a, b, 5e-8)$ 

[a,b]	Root	# Iterations
[-2.5, -2]	-2.1222382	23
[-1.5, -1.25]	-1.4255432	22
[-1.25, -1]	-1.2145933	22
[1, 1.25]	1.2145933	22
[1.25, 1.5]	1.4255432	22
[2, 2.5]	2.1222382	23

(c) The iterative scheme we asked to implement is called Steffensen's method. This is implemented in the steffensenRoot function.

```
function [r, n, err] = steffensenRoot(f, x0, tol, nMax)
    %steffensenRoot uses Steffensen's method to find roots of f(x)
    % based on an initial guess x0
    %
    %Inputs:
    % f = function handle to function whose root is to be found
    % x0 = initial guess of the root to begin iteration at
    % tol = absolute error tolerance with which to find the root
    % iteration terminates when the root is known to within +/- tol
    % nMax = the maximum number of iteration to quit after. Prevents an
    % infinite loop if the iterations do not converge
    %
```

```
% err = 1*n vector of the absolute error after each interation
   %Usage:
   % [r, n, err] = steffensenRoot(@(x) exp(-x) -x, 0, 5e-9, 50) ->
   % returns the approximate roo of x^-x -x = 0 after n iterations and
   % err the absolute error after each iteration
   % set initial guess as first root
   xn = x0;
   %iteration counter
   n = 0;
   % preallocate error array
   err = Inf(1, nMax);
   while all(err > tol) && n < nMax</pre>
      n = n + 1;
      x01d = xn;
      % Calculate f(xn) to avoid repeat computation
      fn = f(xn);
      % Calculate next interation
      xn = xn - fn*(f(xn + fn)/fn - 1)^-1;
      err(n) = abs(xn - x0ld);
   end
   % remove any unused preallocated element in error array
   err(isinf(err)) = [];
   % check if solution converged
   assert(err(end) < tol, "No convergence")</pre>
   r = xn;
end
The following uses this function to find the root of e^{-x} - x = 0 and calculate the convergence.
f = 0(x) exp(-x) - x;
[r, n, e] = steffensenRoot(f, 0, 5e-13, 50)
%% Generate plot of convergence
```

%Outputs:

% r = the approximate root of f(x)=0% n = the number of interations

After 5 iterations the root x = 0.567143290410 is accurate to 12 decimal places.

loglog(e(1:end-1),e(2:end), "bx-", "LineWidth", 2);

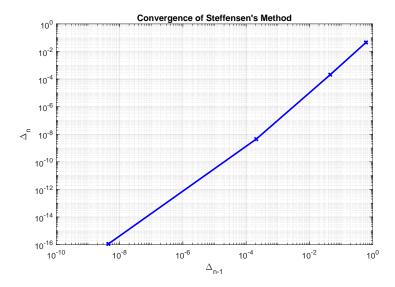

title("Convergence of Steffensen's Method")

polyfit(log(e(1:end-1)), log(e(2:end)), 1)

xlabel('\Delta\_{n-1}');
ylabel('\Delta\_{n}');

%% Find order of congerence

grid on;

The graph shows a straight which shows error  $\propto \Delta_{n-1}^q$ , where q is the gradient of the line. Using the MATLAB function polyfit the gradient of the above graph as 1.8 which is close to 2 so Steffensen's method is second order.

(d) The first step in creating a cobweb plot is to implement a fixed point iteration scheme.

```
function xn = fixedPointRoot(g, x0, nMax)
   % fixedPointRoot Iteration to find solutions of x = g(x)
   %Inputs:
   % g = function handle to find the solutions of <math>x = g(x)
      x0 = first term of the iteration
   % nMax = the maximum number of iteration to quit after
   %Output:
   % xn = the iteraterative sequence
   %Usage:
   % xn = fixedPointRoot(@(x) cos(x), 0.75, 100) \rightarrow looks for a
   \% root of the equation x - cos(x) = 0, starting with an inital guess
      of 0.75.
   % number of iterations
   % preallocated sequence array and set initial guess as first term
   xn = NaN(1, nMax);
   xn(1) = x0;
   % set initial error
   err = Inf;
   % iterate x -> g(x)
   while n < nMax
       n = n + 1;
       xn(n + 1) = g(xn(n));
       err = abs(xn(n + 1) - xn(n));
   end
   % remove any unused elements of the preallocated array
   xn(isnan(xn)) = [];
```

```
fprintf('\nAfter %d steps root is %-20.14g\n', n, xn(end));
   fprintf('Final absolute error is %g\n\n', err);
function cobwebDiagram(g, x0, nMax, a, b)
   \coloredge{Model} %cobwebDiagram Creates cobweb diagram for x = g(x) in interval [a,b]
   %Inputs:
   % g = function handle for g(x)
   % x0 = initial guess to start iteration
   % nMax = number of iterations to complete
   % a = lower end of interval [a,b] to plot cobweb diagram over
   % b = upper end of interval [a,b] to plot cobweb diagram over
   %
   %Usage:
   % cobwebDiagram(@(x) (x.^5 + 3)/5, 1, 10, 0, 1.5) \rightarrow produces a
   % cobweb diagram of x = (x^5 + 3)/5 based on an initial guess of 10
   \% and 10 iterations. This is shown over the interval [0,1.5].
   %% get fixed point iteration sequence
   xn = fixedPointRoot(g, x0, nMax);
   %% generate cobweb diagram
   % get values for the line y = x and y = g(x)
   x = linspace(a, b);
   y = g(x);
   y(isinf(y)) = NaN;
   % set up figure
   hold on;
   grid on;
   set(gca, "DefaultLineLineWidth", 2);
   title("Cobweb plot for fixed point iteration");
   xlabel("x");
   ylabel("y")
   xlim([a b])
   ylim([min(x(1), y(1)) max(x(end), y(end))]);
   % plot lines y = x and y = g(x)
   plot(x, x, "r-", "DisplayName", "y = x");
   plot(x, y, "k-", "DisplayName", "y = g(x)");
   legend("AutoUpdate", "off");
   % plot the steps
   plot([xn(1) xn(1)], [0 xn(2)], 'm-');
   for i=1:length(xn) - 2
       plot([xn(i) xn(i + 1)], [xn(i + 1) xn(i + 1)], 'm-');
       plot([xn(i + 1) xn(i + 1)], [xn(i + 1) xn(i + 2)], 'm-');
end
```

### Question 2: Numerical integration and differentiation

(a) (i) The first expression is Simpson's 3/8 rule and the second is Milne's rule.

```
Simpson's 3/8 rule can be implemented as follows. function quad = simpson38(f, a, b)
```

```
EMAT20920 2020-21 9 Coursework Assessment
```

And similarly Milne's rule can be implemented.
